Abstract

We consider a fluid-structure interaction system composed by a rigid ball immersed into a viscous incompressible fluid. The motion of the structure satisfies the Newton laws and the fluid equations are the standard Navier-Stokes system. At the boundary of the fluid domain, we use the Tresca boundary conditions, that permit the fluid to slip tangentially on the boundary under some conditions on the stress tensor. More precisely, there is a threshold determining if the fluid can slip or not and there is a friction force acting on the part where the fluid can slip. Our main result is the existence of contact in finite time between the ball and the exterior boundary of the fluid for this system in the bidimensional case and in presence of gravity.

Keywords: fluid-structure, Navier-Stokes system, Tresca's boundary conditions

1 Introduction

The system composed by a rigid body and a viscous incompressible fluid, assuming no-slip of the fluid on the solid boundaries, has been studied thoroughly from a mathematical point of view [15, 12, 3, 4, 8, 9]. These results yield that we have similar well-posedness properties as for the fluid alone prior to a possible contact between the rigid body and the exterior boundary. One important issue is then to understand what happens at the time of the contacts if they exist. In [14], the authors show that in dimension 2, if there is a contact between solids, it occurs with null relative velocity and acceleration. Then, in [10, 11] it is proved that for some particular geometry, in dimension 2 or 3 in space, no contact occurs in finite time. For deformable structures, a similar result is proved in [7]. All these results are obtained again under the assumption that the fluid does not slip on the solid boundaries. One of the remedies to recover contacts is to take into account that, in presence of high shear on the boundaries, the fluid should be allowed to slip. One classical model which includes this phenomenon is the Navier slip boundary conditions [13]. For these

Figure 1: Geometry and notations

boundary conditions, the case of an immersed rigid body is studied in [5, 6, 16]. The authors obtain the well-posedness of the corresponding system up to contact and show the existence of contact in finite time between rigid bodies (in dimension 2 and 3). We mention also that the Cauchy theory for a model including slip on the moving body but no-slip on the container boundary is studied in [2].

One drawback of the Navier slip boundary conditions is that it forces the fluid to slip tangentially whatever the size of the shear on the boundaries. A more realistic model are the Tresca boundary conditions. In these boundary conditions, the fluid sticks to the interface up to a shear-rate threshold that the fluid is prevented to exceed by allowing slip on the interface. The boundaries of the fluid domain split then in a zone of small shear rates where Dirichlet boundary conditions are imposed and high shear rates where a type of Navier boundary conditions are imposed (but with an unknown slip length which encodes that the shear rate cannot exceed the threshold value). Discussing whether such models allow contacts or not is a delicate issue. Indeed, the intuitive idea would be to throw sufficiently fast the body toward the container boundary. This would create high shear rate and induce slip on the solid boundaries which do not prevent from contact (again see [6]). Yet, though less singular than the Dirichlet boundary conditions, the Navier boundary conditions also imply a kinetic-energy dissipation that forces the velocity of the moving body to vanish when contact occurs. Hence, one must be careful that this dissipation is not sufficiently fast to decrease the shear rate in a sufficiently large zone below the disk implying that no-slip boundary conditions appear preventing from collision occurrence (see [10]). To discuss this issue, we focus on a simplified 2D symmetric configuration similar to [6, 10, 11]. We focus on the 2D case since the knowledge on the Dirichlet problem shows that contacts occur in the 2D case with more difficulties than in the 3D case.

We describe now the system under consideration in this paper. We assume that the rigid body is a ball of radius 1 and that the container Ω is a rectangle:

$$B_h = B((h+1)e_2, 1), \quad \Omega = (-L, L) \times (0, L'),$$

with (e_1, e_2) the canonical basis of \mathbb{R}^2 , and with $h > 0$ the distance between the rigid body and the container boundary (it will be a function of time in what follows) and $L > 1$, $L' > 2$ two constants. Corresponding to the position B_h of the rigid body, we denote by

$$\Omega_h = \Omega \setminus \overline{B_h}$$

the fluid domain. The equations that govern our fluid-solid system write

$$\begin{cases} \rho_{\mathcal{F}}(\partial_t u + u \cdot \nabla u) - \Delta u + \nabla p &= 0 & \text{in } \Omega_h, \\ \operatorname{div} u &= 0 & \text{in } \Omega_h, \end{cases} \quad (1.1)$$

$$u \cdot n = \lambda e_2 \cdot n \quad \text{on } \partial B_h, \quad (1.2)$$

$$\begin{cases} u \cdot \tau - \lambda e_2 \cdot \tau = 0 & \text{if } |D(u)n \cdot \tau| < 1, \\ \exists \beta \geq 0 \quad u \cdot \tau - \lambda e_2 \cdot \tau = -\beta D(u)n \cdot \tau & \text{if } |D(u)n \cdot \tau| = 1, \end{cases} \quad \text{on } \partial B_h, \quad (1.3)$$

$$u \cdot n = 0 \quad \text{on } \partial \Omega, \quad (1.4)$$

$$\begin{cases} u \cdot \tau = 0 & \text{if } |D(u)n \cdot \tau| < 1, \\ \exists \beta \geq 0 \quad u \cdot \tau = -\beta D(u)n \cdot \tau & \text{if } |D(u)n \cdot \tau| = 1, \end{cases} \quad \text{on } \partial \Omega, \quad (1.5)$$

$$\dot{h} = \lambda, \quad (1.6)$$

$$m\dot{\lambda} = - \int_{\partial B_h} \Sigma(u, p)n \cdot e_2 \, d\gamma - m_a g, \quad (1.7)$$

In the above equations n and τ are the fluid exterior normal and associated tangential unitary vectors,

$$D(u) := \frac{1}{2} \left(\nabla u + (\nabla u)^\top \right), \quad \Sigma(u, p) := 2D(u) - pI_2,$$

m is the mass of the rigid ball. We assume that the rigid body is homogeneous so that $m = \pi\rho_S$ where $\rho_S > 0$ is the constant density of the structure. We also assume that the density of the fluid $\rho_{\mathcal{F}} > 0$ is a positive constant. The constant m_a is equal to $m - \pi\rho_{\mathcal{F}} = \pi(\rho_S - \rho_{\mathcal{F}})$ and we assume $\rho_S > \rho_{\mathcal{F}}$ (so that the ball is falling). We should point out that, since we consider a symmetric configuration, we have that the ball does not rotate which allows us to remove the conservation of linear angular momentum. To simplify, we take the viscosity of the fluid constant and equal to 1. We have also fixed the shear threshold to be equal to 1. Both simplifications are independent and do not restrict the generality. We complement the system with initial data:

$$h(0) = h^0, \quad \lambda(0) = \lambda^0, \quad u(0, \cdot) = u^0 \quad \text{in } \Omega_{h^0}. \quad (1.8)$$

The existence of weak solutions is tackled in dimension 3 in space in [1]. We explain now how to adapt this definition to our framework. For this, we set first:

$$w^* = w_h^* = \begin{cases} e_2 & \text{on } \partial B_h \\ 0 & \text{on } \partial \Omega. \end{cases} \quad (1.9)$$

Then the Tresca boundary conditions (1.2)–(1.5) write

$$(u - \lambda w^*) \cdot n = 0 \quad \text{on } \partial \Omega_h, \quad (1.10)$$

$$\begin{cases} (u - \lambda w^*) \cdot \tau = 0 & \text{if } |D(u)n \cdot \tau| < 1, \\ \exists \beta \geq 0 \quad (u - \lambda w^*) \cdot \tau = -\beta D(u)n \cdot \tau & \text{if } |D(u)n \cdot \tau| = 1, \end{cases} \quad \text{on } \partial \Omega_h. \quad (1.11)$$

We recall that this Tresca boundary conditions admits the following variational formulation [1]:

$$\forall c \in \mathbb{R}, \quad (D(u)n \cdot \tau)c \geq |(u - \lambda w^*) \cdot \tau| - |(u - \lambda w^*) \cdot \tau + c| \quad \text{on } \partial \Omega_h. \quad (1.12)$$

We extend also u by λw^* in B_h , so that $\operatorname{div} u = 0$ in Ω and $u \cdot n = 0$ on $\partial \Omega$ (thanks to (1.10)). If $u \in L^2(\Omega)$, these properties are summarized by the statement $u \in L_\sigma^2(\Omega)$. With these conventions, we say that (u, h) is a weak solution of (1.1)–(1.8) on $(0, T)$ if

$$h \in W^{1,\infty}(0, T), \quad 0 < h < L' - 2, \quad \dot{h} = \lambda \quad (1.13)$$

$$u \in L^\infty(0, T; L_\sigma^2(\Omega)), \quad u = \lambda e_2 \text{ in } B_h, \quad u|_{\Omega_h} \in L^2(0, T; H^1(\Omega_h)), \quad (1.14)$$

and if, for any (w, ℓ) satisfying

$$w \in C^1([0, T]; L_\sigma^2(\Omega)), \quad w = \ell e_2 \text{ in } B_h, \quad \ell \in C^1([0, T]), \quad w|_{\Omega_h} \in L^\infty(0, T; H^1(\Omega_h)), \quad (1.15)$$

there holds:

$$\begin{aligned} \frac{d}{dt} \left[\int_{\Omega_h} \rho_{\mathcal{F}} u \cdot w \, dx + m\lambda \ell \right] - \int_{\Omega_h} \rho_{\mathcal{F}} u \cdot (\partial_t w + (u \cdot \nabla) w) \, dx - m\lambda \dot{\ell} + \int_{\Omega_h} 2D(u) : D(w) \, dx \\ + m_a g \ell + 2 \int_{\partial\Omega_h} |(u - \lambda w^*) \cdot \tau| - |[u - w - (\lambda - \ell)w^*] \cdot \tau| \, d\gamma \leq 0. \end{aligned} \quad (1.16)$$

This last identity is obtained by multiplying (1.1) by w , integrating by parts, introducing (1.7) and reformulating boundary terms thanks to (1.12). With similar arguments as in [1], one obtains the following result for our system:

Theorem 1.1. *Assume $(h^0, \lambda^0) \in (0, L' - 2) \times \mathbb{R}$ and $u^0 \in L^2(\Omega_{h^0})$ satisfy:*

$$\operatorname{div} u^0 = 0, \quad u^0 \cdot n = \lambda^0 w^* \cdot n \quad \text{on } \partial\Omega_{h^0}.$$

Then, there exist $T > 0$ and a weak solution (u, h) of (1.1)–(1.8) on $(0, T)$ that satisfies:

$$\begin{aligned} \sup_{(0, T)} \left[\frac{1}{2} \int_{\Omega} \rho |u|^2 \, dx + m_a g h \right] + 2 \int_0^T \int_{\Omega_{h(t)}} |D(u)|^2 \, dx \, dt + 2 \int_0^T \int_{\partial\Omega} |u - \lambda w^*| \, d\gamma \, dt \\ \leq \frac{1}{2} \int_{\Omega} \rho^0 |u^0|^2 \, dx + m_a g h^0. \end{aligned} \quad (1.17)$$

Furthermore we have the following alternative:

- $T = \infty$
- $T < \infty$ and $\left(\lim_{t \rightarrow T} h(t) = 0 \text{ or } \lim_{t \rightarrow T} h(t) = L' - 2 \right)$

We omit the proof for conciseness. The main objective of this paper is to prove that the second alternative can occur, meaning that the rigid ball can touch the exterior boundary in finite time. To this end, we are going to assume that the initial velocity of the body vanishes. We fix $u^0 \in L^2(\Omega_{h^0})$ and $\rho_{\mathcal{F}}$ and take m large enough and h^0 small enough. Our main result reads then:

Theorem 1.2. *Given $\lambda^0 = 0$ and $u^0 \in L^2(\Omega_{h^0})$. For h^0 small enough and $m h^0$ large enough, there exist $T \in (0, \infty)$ and a weak solution (u, h) such that*

$$\lim_{t \rightarrow T} h(t) = 0.$$

The proof of Theorem 1.2 is based on analysing the properties of the solution inherited from Theorem 1.1. To this end, we construct a particular family of test functions in the same spirit as in [10, 11, 6, 16]. We use this family in our variational inequality and this leads us to a differential inequality on h where appears a term of order $\ln(h)$ due to our boundary conditions. Using this differential inequality and taking m large enough and h^0 small enough, we show Theorem 1.2.

The outline of the paper is as follows. In the next section, we present the most novel arguments of our analysis: an adapted Korn inequality and the treatment of the differential inequality leading to contact. In the last section, we introduce the weak formulation of our problem, discuss the construction of a particular family of test functions and we use these test functions in our weak formulation to deduce the expected differential inequality on h .

2 Main steps in the proof of Theorem 1.2

We provide in this section two major steps in the proof of Theorem 1.2. The first one consists of a Korn inequality. We recall that such inequalities are introduced to control the L^p -norm of a full gradient by the same L^p -norm of the symmetric part of this gradient. Such inequalities are classical but, in our case, we are specifically interested in the dependence of the constant appearing in this inequality on geometrical parameters (especially the distance h). So, we give here a detailed analysis of this point. Moreover, it turns out that we control a supplementary term which helps a lot the analysis. The second part of this section is devoted to the final step in the proof of Theorem 1.2. Thanks to a multiplier argument we obtain in next section a differential inequality for the distance h . We show in this section that this differential inequality yields to finite-time contact.

2.1 An adapted Korn inequality

In the whole subsection $h > 0$ and we consider functional inequalities in the associated domains Ω_h and B_h . We restrict to values of h lower than some fixed $h^0 \in (0, L' - 2)$ since we want to consider possible contacts with the bottom boundary of Ω only. Given $h \in (0, L' - 2)$, we set:

$$V^1(h) := \{u \in L^2(\Omega) ; u \in H^1(\Omega_h), \quad \operatorname{div} u = 0 \quad \text{in } \Omega, \quad u \cdot n = 0 \quad \text{on } \partial\Omega, \quad \nabla u = 0 \quad \text{in } B_h\}.$$

We note that, given $u \in V^1(h)$ there exists a unique $\lambda_u \in \mathbb{R}^2$ such that $u = \lambda_u$ in B_h . Since u is globally divergence-free on Ω , we have also that

$$u \cdot n = \lambda_u \cdot n \quad \text{on } \partial B_h.$$

We start with estimating λ_u :

Lemma 2.1. *Assume $h \in (0, h^0)$ and $u \in V^1(\Omega_h)$. Then $\lambda = \lambda_u$ satisfies*

$$|\lambda|^2 \leq C_1 \int_{\Omega_h} |D(u)|^2 dx.$$

for a constant C_1 depending only on L, L', h^0 .

Proof. We set

$$\Omega_h^+ = \{x \in \Omega_h ; x_2 > 1 + h\}.$$

This is a locally Lipschitz domain as long as $0 < h < L' - 2$. Assume $u \in V^1(h)$, we write

$$0 = \int_{\Omega_h^+} \operatorname{div} u \, dx = \int_{\partial\Omega_h^+} u \cdot n \, ds = - \int_{\Gamma_1} u_2 \, ds + \lambda \cdot \int_{\Gamma_2} n \, ds,$$

where $\Gamma_1 = \{(x_1, 1 + h) ; x_1 \in (-L, -1) \cup (1, L)\}$ and $\Gamma_2 = \partial B_h \cap \partial\Omega_h^+$. We deduce from the above relation that

$$\lambda_2 = -\frac{1}{2} \int_{(-L, -1) \cup (1, L)} u_2(x_1, 1 + h) \, dx_1.$$

Using that for almost every $x_1 \in (-L, -1) \cup (1, L)$, $u_2(x_1, \cdot) \in H^1((1 + h, L'))$ and $u_2(x_1, L') = 0$, we deduce that

$$|\lambda_2| \leq \frac{1}{2} \int_{\Omega_h} |\partial_2 u_2(x)| \, dx \leq C \|D(u)\|_{L^2(\Omega_h)}.$$

We can proceed similarly for λ_1 by integrating the divergence-free condition on $\Omega_h^r = \{x \in \Omega_h ; x_1 > 0\}$ and we deduce the result. \square

We can now prove the following result:

Lemma 2.2. *Assume $h \in (0, h^0)$ and $u \in V^1(h)$. Then there exists a constant C depending only on L, L', h^0 such that*

$$\int_{\Omega_h} |\nabla u|^2 \, dx + \int_{\partial B_h} |u|^2 \, ds \leq C \int_{\Omega_h} |D(u)|^2 \, dx.$$

Proof. Using a density argument, we can assume that $u \in C^\infty(\overline{\Omega_h})$. First, we have

$$2 \int_{\Omega_h} |D(u)|^2 \, dx = \int_{\Omega_h} (\nabla u + (\nabla u)^\top) : \nabla u \, dx.$$

By integration by parts and using that $\operatorname{div} u = 0$, we deduce

$$2 \int_{\Omega_h} |D(u)|^2 \, dx = \int_{\Omega_h} |\nabla u|^2 \, dx + \int_{\partial\Omega} [(u \cdot \nabla)u] \cdot n \, ds + \int_{\partial B_h} [(u \cdot \nabla)u] \cdot n \, ds,$$

where we recall that n is the unit outer normal to Ω_h . Using that $u \cdot n = 0$ on $\partial\Omega$ and that Ω is a rectangle, we deduce

$$\int_{\partial\Omega} [(u \cdot \nabla)u] \cdot n \, ds = 0.$$

Finally, we compute the boundary integral on ∂B_h . For this, we introduce (r, θ) the cylindrical coordinates centered in the center of B_h and (e_r, e_θ) the associated local basis. We have then $n = -e_r$ and, writing differential operators in terms of (r, θ) coordinates, we obtain:

$$(u \cdot \nabla)u \cdot e_r = u_r \partial_r u_r + \frac{1}{r} u_\theta \partial_\theta u_r - \frac{1}{r} u_\theta^2$$

and

$$\operatorname{div} u = \partial_r u_r + \frac{u_r}{r} + \frac{\partial_\theta u_\theta}{r} = 0.$$

This yields

$$\int_{\partial B_h} [(u \cdot \nabla)u] \cdot n \, ds = \int_{\partial B_h} |u|^2 \, ds - 2 \int_0^{2\pi} u_\theta \partial_\theta u_r \, d\theta.$$

Here, we may apply that $u_r = -\lambda \cdot e_r$ on ∂B_h so that we can dominate:

$$\left| 2 \int_0^{2\pi} u_\theta \partial_\theta u_r \, d\theta \right| \leq C|\lambda|^2 + \frac{1}{2} \int_{\partial B_h} |u|^2 \, ds.$$

Finally, we obtain that

$$2 \int_{\Omega_h} |D(u)|^2 \, dx \geq \int_{\Omega_h} |\nabla u|^2 \, dx + \frac{1}{2} \int_{\partial B_h} |u|^2 \, ds - C|\lambda|^2.$$

It remains to apply the previous lemma to control the λ term. This ends the proof. \square

Using Poincaré's inequality on u_1 and on u_2 and using that u_1 vanishes on the left/right boundaries (resp. u_2 vanishes on the top/bottom boundaries), we obtain that

$$\int_{\Omega_h} |u|^2 \, dx \leq C \int_{\Omega_h} |D(u)|^2 \, dx,$$

for a constant C depending only on L, L' . As a consequence, we deduce the following result:

Proposition 2.3. *Assume $h \in (0, h^0)$ and $u \in V^1(h)$, there exists a constant C depending only on L, L', h^0 such that*

$$\int_{\Omega_h} |\nabla u|^2 \, dx + \int_{\Omega_h} |u|^2 \, dx + \int_{\partial B_h} |u|^2 \, ds \leq C \int_{\Omega_h} |D(u)|^2 \, dx.$$

To end up this section, we note that this proposition also implies another control of λ . This is the content of the next lemma:

Lemma 2.4. *Assume $h \in (0, h_0)$ and $u \in V^1(h)$, with $u = \lambda e_2$ in B_h . Then*

$$|\lambda| \leq C h^{1/4} \|D(u)\|_{L^2(\Omega_h)}.$$

with a universal constant C .

For a proof, we refer to the arguments leading to Lemma 6.4 in [16] (see inequality (A.15)). We note here that in the proof of [16], we can use the L^2 -norm on ∂B_h instead of the L^2 -norm on $\partial\Omega$. Then, we apply the above Korn inequality to conclude.

2.2 Final step of the proof of Theorem 1.2

Following the assumption of Theorem 1.2, we consider in this subsection that $\lambda^0 = 0$ and that $\rho_{\mathcal{F}}$ and $u_0 \in L^2(\mathcal{F}^0)$ are given. We consider then the weak solution (u, h) provided by Theorem 1.1 for this initial data. This solution is defined on $(0, T)$ where T is finite if contact occurs in time T . We shall prove that, under the assumption that h^0 is sufficiently small and mh^0 is sufficiently large, then T might not exceed some value T_* .

The proof of Theorem 1.2 relies on two ingredients. The first one is a differential inequality derived in the next section. We summarize this result in the following lemma:

Lemma 2.5. *There exist $C^\sharp > 0$ and $C^* > 0$ independent of (m, h_0) such that as long as the distance function h satisfies $h \leq 1$, there holds:*

$$\dot{h}(t) \leq -\frac{gt}{2} + C^\sharp gh^0 + \frac{C^*}{m} \int_0^t |\ln(h(s))| ds. \quad (2.1)$$

The proof of this lemma is postponed to the next section. The second ingredient of the proof is the energy inequality (1.17). In case $\lambda^0 = 0$ the initial energy of the system reads:

$$E^0 := \frac{1}{2} \int_\Omega \rho^0 |u^0|^2 dx + m_a gh^0 = \frac{\rho_F}{2} \int_{\Omega_{h^0}} |u^0|^2 dx + (m - \pi \rho_F) gh^0. \quad (2.2)$$

So, taking mh^0 sufficiently large, we have $E^0 \leq 2mgh^0$ so that energy estimate entails:

$$|\dot{h}(t)| \leq 2\sqrt{gh^0}, \quad \forall t \in (0, T). \quad (2.3)$$

From now on, we suppose (2.3) and (2.1). We fix $\sigma \in (0, 1/2)$ and we choose h^0 sufficiently small and mh^0 sufficiently large so that:

$$\begin{cases} h^0 < \max \left(\frac{2}{3(1+\sigma)}, \frac{1}{(32C^\sharp)^2 g} \right), \\ m \geq \frac{8C^*}{g} \left\{ \left| \ln \frac{h^0}{2} \right| + 3\sigma \left| \ln \left[(1-\sigma) \frac{h^0}{2} \right] \right| \right\}. \end{cases} \quad (2.4)$$

We emphasize that, the two conditions are fixed successively. First h^0 is chosen to fulfill the first condition. This fixes the right-hand side of the second inequality and we might choose a bigger m (which amounts to fix mh^0 sufficiently large). We will take m even larger in what follows (depending on h^0 and σ). We introduce then the sequence of times:

$$\begin{cases} t_0 = \frac{1}{4} \sqrt{\frac{h^0}{g}}, \\ t_{n+1} = t_n + \sigma \frac{h(t_n)}{2\sqrt{gh^0}}, \end{cases} \quad (2.5)$$

and we show

Lemma 2.6. *Given $\sigma \in (0, 1/2)$, h^0 sufficiently small and mh^0 sufficiently large, the times t_n as computed by (2.5) are well defined for all $n \in \mathbb{N}$. Furthermore, for any $n \geq 0$ there holds:*

$$(1-\sigma)^n \frac{h^0}{2} \leq h(t_n) \leq \left(1 - \frac{\sigma^2}{32}\right)^n \frac{3}{2} h^0. \quad (2.6)$$

The proof of this lemma shall end the proof of Theorem 1.2. Indeed, by relation (2.6) and definition (2.5), we have that the sequence of time increments $(t_{n+1} - t_n)_{n \in \mathbb{N}}$ is dominated by a converging geometric sequence. In particular t_n converges increasingly to a finite time T_* with (applying again (2.6)) $\lim_{n \rightarrow \infty} h(t_n) = 0$. Since h is at least continuous we get $h(T_*) = 0$ preventing from $T > T_*$.

Proof of Lemma 2.6. We recall that we assume at first that h^0 and mh^0 are chosen so that (2.4) holds true. We prove by induction that

$$h(t) \in (0, 1), \quad \forall t \in [0, t_n], \quad h(t_n) \text{ satisfies (2.6)}. \quad (\mathcal{P}_n)$$

This entails the expected result.

Case $n = 0$. By (2.3) and the choice of t_0 , there holds:

$$\frac{h^0}{2} \leq h(t) \leq \frac{3h^0}{2} \quad \forall t \in [0, t_0].$$

The restriction on h^0 in (2.4) implies then that $h(t) \in (0, 1)$ for $t \in [0, t_0]$ and $h^0/2 \leq h(t_0) \leq 3h^0/2$.

Induction. Now, fix $n \in \mathbb{N}$ and assume that (\mathcal{P}_k) holds true for all $k \leq n$. First, from (2.3) and (2.5), we have:

$$(1 - \sigma)h(t_n) \leq h(t) \leq (1 + \sigma)h(t_n) \quad \forall t \in [t_n, t_{n+1}].$$

In particular, there holds:

$$(1 - \sigma)^{n+1} \frac{h^0}{2} \leq h(t) \leq (1 + \sigma) \frac{3}{2} h^0 \quad \forall t \in [t_n, t_{n+1}]. \quad (2.7)$$

By choice of h^0 we obtain that $h(t) \in (0, 1)$ for $t \in [t_n, t_{n+1}]$ and thus on $[0, t_{n+1}]$ thanks to the induction assumption. We obtain also already the left-hand inequality in (2.7):

$$(1 - \sigma)^{n+1} \frac{h^0}{2} \leq h(t_{n+1})$$

All that remains concerns the right-hand inequality in (2.7). For this, we note that $h(t) \leq 1$ on $[t_n, t_{n+1}]$ so that (2.1) holds true. We have then, for $t \in [t_n, t_{n+1}]$,

$$\begin{aligned} \dot{h}(t) &\leq -\frac{g}{2}t + C^\sharp gh^0 + \frac{C^*}{m} \int_0^t |\ln(h(s))| ds \\ &\leq -\frac{g}{2}t_0 + C^\sharp gh^0 + \frac{C^*}{m} \int_0^{t_0} |\ln(h(s))| ds + \frac{C^*}{m} \sum_{k=0}^n \int_{t_k}^{t_{k+1}} |\ln(h(s))| ds. \end{aligned}$$

For the first three terms, we apply that $h(t) \in (h^0/2, 1)$ on $(0, t_0)$, the definition of t_0 and the restrictions on h^0 and m to obtain that:

$$-\frac{g}{2}t_0 + C^\sharp gh^0 + \frac{C^*}{m} \int_0^{t_0} |\ln(h(s))| ds \leq -\frac{1}{16} \sqrt{gh^0} + \frac{C^*}{4m} \sqrt{\frac{h^0}{g}} \left| \ln \frac{h^0}{2} \right| \leq -\frac{1}{32} \sqrt{gh^0}.$$

This entails:

$$\dot{h}(t) \leq -\frac{1}{32} \sqrt{gh^0} + \frac{C^*}{m} \sum_{k=0}^n \int_{t_k}^{t_{k+1}} |\ln(h(s))| ds.$$

Introducing again the definition of (t_{k+1}, t_k) and the bound below for $h(t)$ on (t_{k+1}, t_k) (similar to (2.7) on (t_k, t_{k+1})) we deduce that:

$$\dot{h}(t) \leq -\frac{1}{32} \sqrt{gh^0} + \frac{C^*}{m} \sum_{k=0}^N \sigma \frac{h(t_k)}{2\sqrt{gh^0}} \left| \ln \left[(1 - \sigma)^{k+1} \frac{h^0}{2} \right] \right|.$$

Introducing the bound above taken from (2.6) for $h(t_k)$ in the remaining sum, we deduce that:

$$\dot{h}(t) \leq -\frac{1}{32} \sqrt{gh^0} + \frac{3C^*\sigma}{4m} \sqrt{\frac{h^0}{g}} \sum_{k=0}^N \left(1 - \frac{\sigma^2}{32} \right)^k \left| \ln \left[(1 - \sigma)^{k+1} \frac{h^0}{2} \right] \right|.$$

Since $\sigma \in (0, 1/2)$ and the series

$$\left(\sum_{k=0}^n \left(1 - \frac{\sigma^2}{32} \right)^k \left| \ln \left[(1 - \sigma)^{k+1} \frac{h^0}{2} \right] \right| \right)_n$$

is convergent, we may increase the value of m so such that:

$$-\frac{1}{32} \sqrt{gh^0} + \frac{3C^*\sigma}{4m} \sqrt{\frac{h^0}{g}} \sum_{k=0}^n \left(1 - \frac{\sigma^2}{32} \right)^k \left| \ln \left[(1 - \sigma)^{k+1} \frac{h^0}{2} \right] \right| \leq -\frac{\sigma}{16} \sqrt{gh^0}. \quad (2.8)$$

Integrating this bound above for $\dot{h}(t)$ between t_n and t_{n+1} we conclude that:

$$h(t_{n+1}) - h(t_n) \leq -\frac{\sigma^2}{32} h(t_n)$$

This ends up the proof. \square

3 Proof of Lemma 2.5

The proof of Lemma 2.5 is obtained by choosing a suitable test-function in the weak formulation of (1.1)–(1.8). We exhibit now this test-function. The construction is by now classical (see [10, 11] among other). The main point is to define the test-function below the disk. So, given $h \leq 1$, we set \mathcal{G}_h the subdomain of Ω_h defined by

$$\mathcal{G}_h := \left\{ x \in \mathbb{R}^2 ; |x_1| < \frac{1}{4} \quad x_2 \in (0, H(x_1)) \right\},$$

where H is a graph-parametrization of the bottom part of the disk boundary:

$$H(x_1) := h + \gamma(x_1), \quad \gamma(x_1) = 1 - \sqrt{1 - x_1^2}. \quad (3.1)$$

We also define

$$\mathcal{G}_h^{1/2} := \left\{ x \in \mathbb{R}^2 ; |x_1| < \frac{1}{2} \quad x_2 \in (0, H(x_1)) \right\}.$$

We choose δ sufficiently small so that:

$$\forall h \leq 1, \quad \{(x_1, x_2) \notin \mathcal{G}_h ; |(x_1, x_2) - (0, 1 + h)| \in [1 + \delta, 1 + 2\delta]\} \subset \Omega.$$

Then, in $\mathcal{G}_h^{1/2}$, we define

$$a(h, x_1) = \mu_1 h + \mu_2 x_1^2, \quad (3.2)$$

and

$$\phi_s(x_1, x_2) = x_1 \left[(1 - a(h, x_1)) \frac{x_2}{H(h, x_1)} + a(h, x_1) \left(\frac{x_2}{H(h, x_1)} \right)^3 \right],$$

with $\mu_1 = 1/6, \mu_2 = -3/2$. This formula corresponds to the stream function of w_h below the disk. We choose to keep abstract letter μ_1, μ_2 to emphasize from where these explicit values come from in computations. We also consider (with δ chosen above) $\phi : \mathbb{R}^2 \rightarrow \mathbb{R}$ such that

$$\phi(x_1, x_2) = \begin{cases} x_1 & \text{if } |(x_1, x_2)| < 1 + \delta, \\ 0 & \text{if } |(x_1, x_2)| \geq 1 + 2\delta, \end{cases}$$

and we set:

$$\phi_0(x_1, x_2) = \phi((x_1, x_2) - (0, 1 + h)).$$

Finally, our test-function reads in Ω_h :

$$w_h = \nabla^\perp \Psi = \begin{bmatrix} -\partial_2 \Psi \\ \partial_1 \Psi \end{bmatrix} \quad \text{where } \Psi = \begin{cases} (\chi \phi_0 + (1 - \chi) \phi_0) & \text{in } \mathcal{G}_h \\ \phi_0 & \text{in } \Omega_h \setminus \mathcal{G}_h \end{cases} \quad (3.3)$$

where $\chi : \mathbb{R}^2 \rightarrow \mathbb{R}$ is a smooth function such that

$$\chi(x_1, x_2) = \begin{cases} 1 & \text{in } \left(-\frac{1}{4}, \frac{1}{4} \right)^2, \\ 0 & \text{in } \mathbb{R}^2 \setminus \left[-\frac{1}{2}, \frac{1}{2} \right]^2. \end{cases} \quad (3.4)$$

Concerning this test-function, we have the following proposition:

Proposition 3.1. *For any $h \leq 1$, the test-function w_h enjoys the properties:*

$$\operatorname{div} w_h = 0 \quad \text{in } \Omega_h, \quad (w_h - w^*) \cdot n = 0 \quad \text{on } \partial\Omega_h, \quad 2D(w_h)n \cdot \tau = 0 \quad \text{on } \partial\Omega, \quad (3.5)$$

Moreover, there exists a constant C independent of h such that:

$$\|w_h\|_{L^2(\mathcal{G}_h)} + \left\| \int_0^{x_2} \partial_h w_{h,1} \right\|_{L^2(\mathcal{G}_h)} + \left\| \int_0^{x_2} \nabla w_h \right\|_{L^\infty(\mathcal{G}_h)} \leq C, \quad (3.6)$$

$$\|2D(w_h)n \cdot \tau\|_{L^\infty(\partial B_h)} + \left\| \int_0^H \nabla w_h \right\|_{L^\infty(-1/2, 1/2)} \leq C \quad (3.7)$$

$$\frac{1}{|\ln(h)|} \int_{\partial\Omega_h} |[w_h - w^*] \cdot \tau| \, d\gamma \leq C, \quad (3.8)$$

$$h^{\frac{1}{4}} \left(\|\nabla w_h\|_{L^2(\mathcal{G}_h)} + \|\partial_h w_{h,2}\|_{L^2(\mathcal{G}_h)} + \|w_h\|_{L^2(\partial B_h \cap \partial\mathcal{G}_h)} + \left[\int_{-1/2}^{1/2} \left(\int_0^H \partial_h w_{h,1} \, dz \right)^2 dx_1 \right]^{1/2} \right) \leq C, \quad (3.9)$$

and there exists a pressure q_h such that, with a constant C independent of h :

$$\|\Delta w_h - \nabla q_h\|_{L^2(\mathcal{G}_h)} \leq C, \quad h^{\frac{1}{2}} \left| e_2 \cdot \int_{\partial B_h} \Sigma(w_h, q_h) n d\gamma \right| \leq C. \quad (3.10)$$

Outside the gap, we have, with a constant C independent of h :

$$\|w_h\|_{L^2(\Omega \setminus \mathcal{G}_h)} + \|\partial_h w_h\|_{L^2(\Omega \setminus \mathcal{G}_h)} + \|\nabla w_h\|_{L^\infty(\Omega \setminus \mathcal{G}_h)} + \|\Delta w_h\|_{L^2(\Omega \setminus \mathcal{G}_h)} + \|\nabla q_h\|_{L^2(\Omega \setminus \mathcal{G}_h)} \leq C. \quad (3.11)$$

Proof. The proof of this lemma is made of long and tedious computations. We recall that they are based on the explicit formulas for w_h . Beyond these explicit formulas, the main tools are a comparison between powers of x_2 and x_1 appearing in the numerators with powers of H appearing on the denominator. For this, we point out that $x_2 \leq H$ while $|x_1| \leq \sqrt{H}$ in \mathcal{G}_h . After reduction of formulas based on these comparisons, computing Sobolev norms reduces to the following estimates of integrals:

$$\int_{-1/4}^{1/4} \frac{|x_1|^e}{H(x_1)^p} dx_1 \leq \begin{cases} |\ln(h)| & \text{if } e = 1 \text{ and } p = 1 \\ h^{1-p} & \text{if } e = 1 \text{ and } p \geq 2 \\ h^{1/2-p} & \text{if } e = 0 \text{ and } p \geq 1 \end{cases}$$

We only provide the computation of the L^∞ -norm of $2D(w_h)n \cdot \tau$ on ∂B_h to explain the choice of μ_1 and μ_2 . Explicit computations show that, on $\partial B_h \cap \partial\mathcal{G}_h^{1/2}$, we have:

$$2D(w)n \cdot \tau = \frac{x_1 h(1 - 6\mu_1) - x_1^3(3/2 + \mu_2)}{H^2} + O(1).$$

where O corresponds to a bounded function in x_1 independently of h . We see here that, taking $\mu_1 = 1/6$ and $\mu_2 = -3/2$, we compensate the diverging terms and obtain that $2D(w_h)n \cdot \tau$ remains bounded independent of h .

To conclude the proof, we provide the construction of the pressure q_h which is slightly different from previous computations due to the form of the function a . From the definition of w_h , we deduce

$$\Delta w = \begin{bmatrix} -\partial_{112}\Psi - \partial_{222}\Psi \\ \partial_{111}\Psi + \partial_{122}\Psi \end{bmatrix} \quad \text{in } \Omega_h.$$

We then set $q_h = \chi \tilde{q}_h$ in \mathcal{G}_h (χ is the truncation function above) that we extend by 0 and where, for $x \in \mathcal{G}_h$:

$$q_h(x) = \int_{-1/2}^{x_1} \frac{-6sa}{H^3} ds + \partial_{12}\Psi + 2 \int_{-1/2}^{x_1} (1-a) \left(\frac{2H'}{H^2} - s \left(2\frac{(H')^2}{H^3} - \frac{H''}{H^2} \right) \right) ds - \frac{3x_2^2}{2} \left(\frac{H''}{H^2} - 2\frac{(H')^2}{H^3} \right) + x_1 \left(\frac{3H''H'}{H^3} - 3\frac{(H')^3}{H^4} - \frac{H'''}{2H^2} \right) x_2^2. \quad (3.12)$$

To give the idea of such a choice, the first integral cancels $\partial_{222}\Psi$ in $\Delta w_{h,1}$ while the second one cancels $\partial_{122}\Psi$. Doing so, we have left a term $-2\partial_{112}\Psi$ in $\Delta w_{h,1} - \partial_1 q_h$ and a term $\partial_{122}\Psi$ in $\Delta w_{h,2} - \partial_2 q_h$. Unfortunately, diverging terms remain in these quantities that we compensate with the remaining explicit terms of the pressure. Indeed, with this choice, we obtain that

$$|\Delta w_h - \nabla q_h| \leq C \left(1 + \frac{|x_1|}{H} \right) \quad \text{in } \mathcal{G}_h$$

which entails the expected result. Before ending the proof, we also mention that we choose the integrals in q_h starting from $-1/2$ in order to avoid the introduction of diverging term when operating the truncation by χ . Due to the symmetries of the integrated functions, we could as well have chosen to start from $1/2$.

To conclude, standard integration by parts using boundary conditions satisfied by w_h entail that:

$$\begin{aligned} e_2 \cdot \int_{\partial B_h} \Sigma(w_h, q_h) n d\gamma &= \int_{\partial \Omega_h} w_h \cdot \Sigma(w_h, q_h) n d\gamma + \int_{\partial \Omega_h} ((w^* - w_h) \cdot \tau) (2D(w_h) n \cdot \tau) d\gamma \\ &= \int_{\Omega_h} w_h \cdot (\Delta w_h - \nabla q_h) dx + 2 \int_{\Omega_h} |D(w_h)|^2 dx + \int_{\partial B_h} ((w^* - w_h) \cdot \tau) (2D(w_h) n \cdot \tau) d\gamma. \end{aligned}$$

Introducing in this relation the previous results of the proposition we obtain the expected bound. This concludes the proof of the proposition. \square

Now, we consider a weak solution (u, h) on $[0, T]$ and we assume that $0 < h \leq 1$. We take the test function w_h obtained in Proposition 3.1 in the weak formulation (1.16). Noticing that we have $\ell = 1$ in this case, integrating by parts and introducing the pressure, we obtain:

$$\begin{aligned} \frac{d}{dt} \left[\int_{\Omega_h} \rho_{\mathcal{F}} u \cdot w dx + m\dot{h} \right] &- \int_{\Omega_h} \rho_{\mathcal{F}} u \cdot (\partial_t w + (u \cdot \nabla) w) dx + \int_{\Omega_h} u \cdot (-\Delta w + \nabla q) dx \\ &+ 2 \int_{\partial \Omega_h} (u - \lambda w^*) \cdot \tau (D(w) n \cdot \tau) d\gamma + \dot{h} e_2 \cdot \int_{\partial B_h} \Sigma(w, q) n d\gamma \\ &+ m_a g \leq 2 \int_{\partial \Omega_h} |[u + w - (\lambda + 1)w^*] \cdot \tau| - |(u - \lambda w^*) \cdot \tau| d\gamma. \end{aligned} \quad (3.13)$$

We introduce now $\Phi \in C^1((0, 1])$ such that

$$\Phi'(h) = e_2 \cdot \int_{\partial B_h} \Sigma(w_h, q_h) n d\gamma. \quad (3.14)$$

and we rewrite (3.13):

$$\begin{aligned} \frac{d}{dt} \left[\int_{\Omega_h} \rho_{\mathcal{F}} u \cdot w dx + m\dot{h} + \Phi(h) + m_a g t \right] &- \int_{\Omega_h} \rho_{\mathcal{F}} u \cdot (\partial_t w + u \cdot \nabla w) dx + \int_{\Omega_h} u \cdot (-\Delta w + \nabla q) dx \\ &+ 2 \int_{\partial \Omega_h} (u - \lambda w^*) \cdot \tau (D(w) n \cdot \tau) d\gamma \leq 2 \int_{\partial \Omega_h} |[w - w^*] \cdot \tau| d\gamma. \end{aligned} \quad (3.15)$$

For t arbitrary in $(0, T)$, we integrate this last relation and use the explicit time-dependency of (w_h, q_h) with $\lambda^0 = 0$ to obtain:

$$\begin{aligned} m\dot{h}(t) + \Phi(h(t)) + m_a g t &\leq \left[\int_{\Omega_{h(s)}} \rho_{\mathcal{F}} u(s, x) \cdot w_{h(s)}(x) dx \right]_{s=t}^{s=0} + \Phi(h^0) \\ &+ \int_0^t \int_{\Omega_h} \rho_{\mathcal{F}} u \cdot (\dot{h} \partial_h w_h + u \cdot \nabla w_h) dx ds \\ &+ \int_0^t \int_{\Omega_h} u \cdot (\Delta w_h - \nabla q_h) dx ds \\ &- 2 \int_0^t \int_{\partial \Omega_h} (u - \lambda w^*) \cdot \tau (D(w_h) n \cdot \tau) d\gamma ds \\ &+ 2 \int_0^t \int_{\partial \Omega_h} |[w_h - w^*] \cdot \tau| d\gamma ds. \end{aligned} \quad (3.16)$$

We proceed by estimating the different terms on the right-hand side of this inequality. Below, we denote by C_w any constant depending on our chosen test-functions and on the geometry but independent on h . We extract the dependencies on the other parameters explicitly and thus provide the extensive computations below to conclude the proof.

From (1.17), (3.6) and (3.11), we have

$$\left[\int_{\Omega_h} \rho_{\mathcal{F}} u \cdot w_h \, dx \right]_{s=t}^{s=0} \leq C_w \sqrt{\rho_{\mathcal{F}} E^0}, \quad (3.17)$$

where we recall that E^0 is defined by (2.2). To compute the second term, we decompose:

$$\int_0^t \int_{\Omega_h} \rho_{\mathcal{F}} u \cdot (\dot{h} \partial_h w + u \cdot \nabla w_h) \, dx \, ds = \int_0^t \rho_{\mathcal{F}} \dot{h} \int_{\Omega_h} \partial_h w_h \cdot u \, dx \, ds + \int_0^t \rho_{\mathcal{F}} \int_{\Omega_h} u \cdot \nabla w_h \cdot u \, dx \, ds. \quad (3.18)$$

To estimate the first term in the right-hand side of (3.18), we split Ω_h into the domains \mathcal{G}_h and $\Omega_h \setminus \mathcal{G}_h$. Combining (3.11), Proposition 2.3 and Lemma 2.1 yields

$$\begin{aligned} \left| \rho_{\mathcal{F}} \int_0^t \dot{h} \int_{\Omega_h \setminus \mathcal{G}_h} u \cdot \partial_h w \, dx \, ds \right| &\leq C_w \rho_{\mathcal{F}} \int_0^t |\dot{h}| \left(\int_{\Omega_h} |u|^2 \, dx \right)^{\frac{1}{2}} \leq C_w \rho_{\mathcal{F}} \int_0^t \int_{\Omega_h} |D(u)|^2 \, dx \, ds \\ &\leq C_w \rho_{\mathcal{F}} E^0. \end{aligned}$$

In the domain \mathcal{G}_h , we apply (3.6), (3.7) and (3.9)

$$\begin{aligned} \left| \int_{\mathcal{G}_h} \rho_{\mathcal{F}} u \cdot (\dot{h} \partial_h w) \, dx \right| &\leq \rho_{\mathcal{F}} |\dot{h}| \left[\left| \int_{\mathcal{G}_h} u_1 \partial_2 \left(\int_0^{x_2} \partial_h w_{h,1} \, dz \right) \, dx \right| + \left| \int_{\mathcal{G}_h} u_2 \partial_h w_{h,2} \, dx \right| \right] \\ &\leq \rho_{\mathcal{F}} |\dot{h}| \left[\left| \int_{\mathcal{G}_h} \partial_2 u_1 \left(\int_0^{x_2} \partial_h w_{h,1} \, dz \right) \, dx \right| + \|u\|_{L^2(\partial B_h)} \left[\int_{-1/2}^{1/2} \left(\int_0^H \partial_h w_{h,1} \, dz \right)^2 \, dx_1 \right]^{1/2} \right. \\ &\quad \left. + \left| \int_{\mathcal{G}_h} u_2 \partial_h w_{h,2} \, dx \right| \right] \leq C_w \rho_{\mathcal{F}} |\dot{h}| \left[\|\nabla u_1\|_{L^2(\Omega_h)} + \|u\|_{L^2(\partial B_h)} |h|^{-1/4} + \|u_2\|_{L^2(\Omega_h)} |h|^{-1/4} \right]. \end{aligned}$$

Consequently, applying Lemma 2.4, Proposition 2.3 and (1.17), we conclude that

$$\left| \int_0^t \int_{\mathcal{G}_h} \rho_{\mathcal{F}} u \cdot (\dot{h} \partial_h w) \, dx \, ds \right| \leq C_w \rho_{\mathcal{F}} \int_0^t \int_{\Omega_h} |D(u)|^2 \, dx \, ds \leq C_w \rho_{\mathcal{F}} E^0.$$

Outside the gap, we refer to Proposition 2.3 and Lemma 2.4, Proposition 2.3 and (1.17) to yield again that:

$$\left| \int_0^t \int_{\Omega_h \setminus \mathcal{G}_h} \rho_{\mathcal{F}} u \cdot (\dot{h} \partial_h w) \, dx \, ds \right| \leq C_w \rho_{\mathcal{F}} \int_0^t \int_{\Omega_h} |D(u)|^2 \, dx \, ds \leq C_w \rho_{\mathcal{F}} E^0.$$

We conclude that:

$$\left| \int_0^t \int_{\Omega_h} \rho_{\mathcal{F}} u \cdot (\dot{h} \partial_h w) \, dx \, ds \right| \leq C_w \rho_{\mathcal{F}} E^0. \quad (3.19)$$

As for the other term in the right-hand side of (3.18), we have again:

$$\rho_{\mathcal{F}} \int_{\Omega_h} (u \cdot \nabla) w_h \cdot u \, dx = \rho_{\mathcal{F}} \int_{\mathcal{G}_h} (u \cdot \nabla) w_h \cdot u \, dx + \rho_{\mathcal{F}} \int_{\Omega_h \setminus \mathcal{G}_h} (u \cdot \nabla) w_h \cdot u \, dx.$$

Using (3.11) and Proposition 2.3 entails:

$$\left| \int_0^t \rho_{\mathcal{F}} \int_{\Omega_h \setminus \mathcal{G}_h} u \cdot \nabla w_h \cdot u \, dx \, ds \right| \leq C_w \rho_{\mathcal{F}} E^0.$$

For the other integral, we integrate by parts:

$$\begin{aligned} \int_{\mathcal{G}_h} u \cdot \nabla w_h \cdot u \, dx &= \int_{-1/4}^{1/4} (u \otimes u)(x_1, H(x_1)) : \left[\int_0^{H(x_1)} \nabla w_h \, dz \right] \, dx_1 \\ &\quad - \int_{\mathcal{G}_h} \partial_2 (u \otimes u) : \left(\int_0^{x_2} \nabla w_h \, dz \right) \, dx \end{aligned}$$

and we apply here (3.6), (3.7) and Proposition 2.3 to obtain

$$\begin{aligned} \rho_{\mathcal{F}} \left| \int_0^t \int_{\mathcal{G}_h} u \cdot \nabla w_h \cdot u \, dx \, ds \right| &\leq C_w \rho_{\mathcal{F}} \int_0^t \int_{\Omega_h} |D(u)|^2 \, dx \, ds \\ &\leq C_w \rho_{\mathcal{F}} E^0. \end{aligned}$$

We have finally obtained that:

$$\left| \int_0^t \int_{\Omega_h} \rho_{\mathcal{F}} u \cdot (\dot{h} \partial_h w + u \cdot \nabla w_h) \, dx \right| \leq C_w \rho_{\mathcal{F}} E^0. \quad (3.20)$$

We proceed with the term on the third line of (3.16). Using (3.10) and (3.11), we have:

$$\begin{aligned} \left| \int_0^t \int_{\Omega_h} u \cdot (-\Delta w_h + \nabla q_h) \, dx \, ds \right| &\leq \left(\int_0^t \|u\|_{L^2(\Omega_h)} \, ds \right) \| -\Delta w_h + \nabla q_h \|_{L^\infty(L^2(\Omega_h))} \\ &\leq C_w \sqrt{t} \|Du\|_{L^2(L^2(\Omega_h))} \leq C_w \sqrt{t E^0} \leq C_w E^0 + t. \end{aligned} \quad (3.21)$$

Concerning the term on the fourth line of (3.16), from (3.7), Korn inequality and the energy inequality (1.17), we obtain:

$$\left| \int_0^t \int_{\partial\Omega_h} (u - \lambda w^*) \cdot \tau \, (D(w_h) n \cdot \tau) \, d\gamma \, ds \right| \leq C_w \int_0^t \int_{\partial\Omega_h} |u - \lambda w^*| \, d\gamma \, ds \leq C_w E^0. \quad (3.22)$$

As for the term on the fifth line, recalling (3.8), we have also:

$$\int_0^t \int_{\partial\Omega_h} |[w_h - w^*] \cdot \tau| \, d\sigma \, ds \leq C_w \int_0^t |\ln(h(s))| \, ds. \quad (3.23)$$

Combining (3.17), (3.20), (3.21), (3.22), (3.23) into (3.16), we obtain:

$$\dot{h}(t) \leq \left(-g + \frac{\rho_{\mathcal{F}} \pi + 1}{m} \right) t + \frac{C_0}{m} + \frac{C^*}{m} \int_0^t |\ln(h(s))| \, ds, \quad (3.24)$$

with $C^* = C_w$ and

$$\begin{aligned} C_0 &= C_w (1 + (\rho_{\mathcal{F}} + 1) E^0) + 2 \max_{(0,1)} |\Phi(h)| \\ &= C_w \left(1 + (\rho_{\mathcal{F}} + 1) \left[\frac{\rho_{\mathcal{F}}}{2} \int_{\Omega_{h^0}} |u^0|^2 \, dx + (m - \pi \rho_{\mathcal{F}}) g h^0 \right] \right) + 2 \max_{(0,1)} |\Phi(h)| \end{aligned}$$

Here, we note that C^* is independent of m, h^0 , while choosing $m h^0 = C_1$ sufficiently large (recall that $\pi \rho_{\mathcal{F}} / m < 1$), depending on $\rho_{\mathcal{F}}, g$ and $\|u^0\|_{L^2(\Omega_{h^0})}$, we might bound

$$\begin{aligned} \frac{C_0}{m} &= \left[\frac{C_w}{C_1} \left(1 + (\rho_{\mathcal{F}} + 1) \left[\frac{\rho_{\mathcal{F}}}{2} \int_{\Omega_{h^0}} |u^0|^2 \, dx \right] \right) + \frac{2}{C_1} \max_{(0,1)} |\Phi(h)| \right] h^0 + \left(1 - \frac{\pi \rho_{\mathcal{F}}}{m} \right) g h^0 \\ &\leq 4 g h^0. \end{aligned}$$

We obtain the expected result with $C^\sharp = 4$. This ends the proof of Lemma 2.5.
